

Attention data in Retrieval-Augmented Generation (RAG) refers to how transformer models use internal attention layers to focus on specific retrieved text chunks, compute relevance scores between queries and contexts, and weigh vital facts over noise. [[1](#), [2](#)]

Attention Mechanisms in RAG

- **Context weighting:** Assigns higher score values to text segments that directly address the user prompt.
- **Noise reduction:** Helps the model ignore irrelevant sections found in long retrieved document chunks.
- **Token alignment:** Connects specific words in the user query to matching tokens in the external database results.
